* Photoshop Elements Adobe also produces a version of Photoshop that is more closely geared toward beginners. Photoshop Elements, available at www.adobe.com/products/photoshopel/, costs \$79.95, and it is designed for people who are looking for some basic photo editing tools. The program includes a generous collection of basic editing tools that work with raster images like photographs, drawings, or paintings. You can import photos directly from your camera and place them on a layer so you can work with them separately from your other images. But you lose some of the flexibility of Photoshop's layer-based system, because you can't make the other images on the layer transparent. You don't have the ability to create filters. And you can't layer images that are less than 300 dpi. Adobe's Photoshop Elements comes with a CD and with a companion application for a smart phone or PDA. The companion application makes it possible to send over images and display them in the editor at the same time. The companion applications are available for the iPhone and iPod touch. I recommend that you use a PDF reader or the web browser on a smart phone or PDA to view the image on your mobile device. Photoshop Elements has a unique feature, called Auto Fix, that can reduce mistakes and scratches in images. I consider this feature to be more of an auto-enhancement feature than a true repair feature. Auto Fix works best for images that have a large amount of grain in them. As a result, it's not a great tool for enhancing images of people. With Photoshop Elements, you are limited to using the same photo for any editing project. If you want to save a separate version of an image, you have to use a separate file. If you import images from multiple folders, they all move to the same folder, even if they are in separate subfolders. To make the most of this program, you need to be a bit more specific in your photo editing because it's not as powerful as Photoshop. You need to make sure that you load one photo at a time. Although Photoshop Elements is a good beginner's tool, I don't recommend that you start there. The program lacks many advanced features. This is not a substitute for a more advanced software package. You don't have access to the same built-in features that you do with Photoshop. You can import only 300 dpi images. Adobe recommends

A regular canvas size for Photoshop is 4,000 pixels in length on a side, by 2,000 pixels in height. Note: Most Photoshop Elements canvases are 8,000 pixels by 6,000 pixels, but this can be altered in Custom Image Sizes. As a general rule, the more pixels you have in the canvas, the better your image editing will be. If you have a lot of space (8,000+ pixels on a side) on a canvas, you can crop your image from the top and bottom, keeping as much of the original image as possible. If you have less space, you may want to crop a little from the top or bottom, and it's OK to lose a bit of the image. TIP: When cropping (cutting away) from the sides of a canvas, keep in mind that you will be losing some image. There is a limit to how far you can crop from the sides of a canvas, but if you want more space, consider using custom image sizes instead. In Photoshop, hold down the ALT key (Windows: Ctrl key) and then select the crop tool (or press M or F5) and then click and drag to select the portion you want to keep. Finally, press the ENTER key on your keyboard (Windows: CTRL+Enter). of the mesoporous silicon nanofibers showing a bilayer structure. The inset shows a corresponding SEM image. (d) TEM image of the h-BN-doped Si nanofibers showing a uniform dispersed state, and the inset shows a corresponding SEM image. (e) XPS spectra of C1s, N1s and B1s in the h-BN-doped Si nanofibers. [Fig. 4] Transmission electron microscopy (TEM) images show that the h-BN-doped Si nanofibers are very uniform with diameter of about 60 nm (see Figure 4a), while the un-doped Si nanofibers have diameters of about 30-40 nm (see Figure 4b). Also, this has been verified from the high-resolution TEM (HRTEM) images (see Figure 4c,d) and corresponding selected area electron diffraction (SAED) patterns (see Figure 4d), which showed that the samples had a crystal structure with a (100) plane. We further investigated the phase compositions of the Si nanofibers by X-ray photoelectron spectroscopy (XPS) analysis, as shown in Figure 4e. The B1s peak at 142.8 eV is assigned to the B–N bonds in h-BN. [12] The N1s peak at 400.0 eV is attributed to the sp² hybridized N atoms in Si as well as the pyridinic N. The C1s peak at 284.6 eV originates from the carbon-containing surface groups. [12] The peak positions of the B and N elements are the same as those in h-BN, which demonstrates that the h-BN is successfully doped into the Si nanofibers. The XPS and TEM results show that the h-BN nanofibers can be synthesized via the electrospinning process. Figure 5 shows the Raman spectra of the h-BN-doped Si nanofibers with different doping contents of h-BN. The Raman spectra have also been studied by the Raman mapping technique (see Figure 5a). It can be seen that the Si nanofibers are almost amorphous, with only a tiny amount of the Si-Si bond (Si-Si bond: 738 cm⁻¹), and the E' (symm

So my exact confidence level is: $n = (0.5 + 0.55) * n * n * n = 0.6$ About what rate/amount does this decline happen, or is it different for all individuals? Is it effectively random because I haven't tracked it and don't have enough repetitions to use Poisson regression? I take a similar approach to computable security like a confident idiot. Anything that can be described or computed with confidence can be reliably hacked and I wouldn't accept a claim of security that can't be proven to a 1 in 10³⁰ level of certainty. The most interesting question is - does your approach show that the average person will or won't hack your site? Very simply - no. you have to know someone who can hack it, and then need to study them for a long time to figure out how they do their thing, and replicate their process. Very simply - no. you have to know someone who can hack it, and then need to study them for a long time to figure out how they do their thing, and replicate their process. So that person is trying to hack your site, and you're trying to defend it? Do you have any idea how hard it is to hack a site? It's called a distributed denial of service attack. It's like trying to hack a brick wall. You can make it easier by brute forcing or exploiting a certain vulnerability in the system, but the end result is that you still have a brick wall on your hands. I think Google's attempts to build a stable, secure, robust web-facing system are commendable, but I don't think they are very possible. I'm sure if you took any security system that random hackers would find a way through it. In fact, in this case, I think it is highly probable that your system is easier to hack than the average user. It's just that hacking security and stats is a hard area of research. The odds of someone getting through a brick wall are not high, but the odds of them getting through a steel security system are much lower. As for the 500 concurrent connection (which is roughly the number you tested, and at some point we'd end up in a DoS attack), I'd say that it's highly unlikely for someone to be able to launch a DDoS attack with so many computers. You are right, real hackers would be able to launch a D
